Engineering and ethics related to it are often mentioned in different spaces. As we learned in this class, IEEE has a code of ethics that they recommend that members follow, and in general, people in our discipline follow. We have this because innovation can come at the expense of other people, and allowing that to happen will only cause pain. By having this code, IEEE holds members responsible for their engineering creations and cautions against just working for profit or just for your boss. It asks that you think critically about what your job is and how what you do can impact others. Me personally, when I face a decision where there does not appear to be a clear answer, I ask my peers for guidance and assistance. I believe that the more people that look at a problem the better of a solution that can be created. If all the people who looked at a problem that I had strictly followed the IEEE code of ethics, then we also get the interpretation of multiple people in the project, therefore, many peoples blend of personal and professional ethics. In this process, I am following the Virtue Ethic discipline of fidelity. I am trusting in others to help me make ethical decisions.

However, if I only trusted others to make the decisions, I could make a mistake that could hurt someone, so I also have to consider my personal ethics. Based on what my group members discussed, I appear to have a greater concern for data privacy and protection than some of my peers. I believe that data held by companies should be extremely secure and there should be a higher scrutiny for losing customer data to bad actors. I personally believe that some corporations have too much access to user data and what they hold, and there should be more legal regulation on it because I disagree with ethically holding all of those customers data. My concern comes from, as previously mentioned, data leaks and also because using the customers

as data points can lead to dehumanization of them, but every customer is a human. Therefore, dehumanizing them can hurt them, and I ethically disagree with that.

When I wrote about an ethical dilemma case, I wrote about when Volkswagen cheated the emission test to let subpar cars leak emissions into the atmosphere. They were not honest about the cars that they created, as is evident by the cheating of tests and allowing the cars on the road, so that is a blatant violation of one of the virtues of ethics. There was also a lack of integrity, when the issue was uncovered, it appeared that the company tried to find a person to blame instead of exploring why the issue happened, and more importantly, preventing a belligerent error from happening again. It could also be argued that Volkswagen did not follow the virtue of self-discipline. They seemed worried about maximizing profit instead of creating a safer vehicle for the environment. In a way, they were too worried about profit than they were about people. If instead Volkswagen had put in the effort to manufacture a vehicle that didn't leak emissions, yes it may have taken more time, but they would have been a more "moral" company. They would have shown a care for the earth and the environment that they said that they do. Finally, they wouldn't have lost so much money. As a for profit corporation, the last point is the one that they may most directly care for, but the others should still be considered.
